Problem Statement

Scheduling MC-DAGs on multi-cores

Case Study

Performance tests

#### Research context

- ➤ **Safety-critical systems**: stringent time requirements + software components with different criticalities.
  - Outputs on time.
  - Life-critical, mission-critical and non-critical.
  - Often isolated: architecture or software level.

#### Current industrial trends

- ▶ Reduce size, weight, power consumption, heat.
- ► Integrate and deliver more services.
- ► Multi-core architectures: great processing capabilities
- lacktriangle Large overestimation of execution time ightarrow waste of CPU.

#### Timeliness: WCET estimation

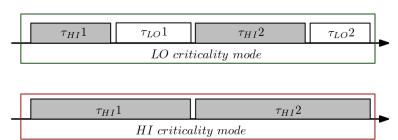

- Real-time systems dimensioned with Worst Case Execution Time (WCET).
- ► Estimating the WCET: a difficult problem<sup>1</sup>.
  - Various methods to obtain an estimate.
  - Multi-core architectures hardly predictable.
  - ► Task rarely executes until its WCET.

<sup>&</sup>lt;sup>1</sup>R. Wilhelm et al. "The worst-case execution-time problem - overview of methods and survey of tools". In: ACM Transactions on Embedded Computing Systems (2008).

## Mixed-Criticality (MC) model

MC model to overcome poor resource usage<sup>2</sup>.

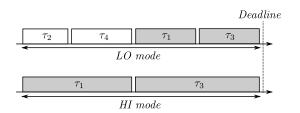

- 1. Different timing budgets.
  - $ightharpoonup C_i(LO)$ : Max. observed execution time (system designers).
  - $ightharpoonup C_i(HI)$ : Upper-bounded execution time (static analysis).
- 2. Incorporate tasks with different criticality levels: HI and LO.
- Execution modes:
  - LO-criticality mode: HI tasks + LO tasks.
  - ▶ HI-criticality mode: **only HI tasks**  $\rightarrow$  LO tasks *discarded*.

<sup>&</sup>lt;sup>2</sup>Steve Vestal. "Preemptive scheduling of multi-criticality systems with varying degrees of execution time assurance". In: *Real-Time Systems Symposium*. IEEE. 2007.

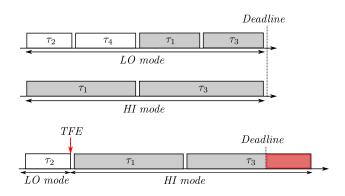

## Schedulability with mode transitions

- **Example:** schedule the task set  $\{\tau_1, \ldots, \tau_4\}$ .
- ▶ HI-criticality tasks:  $\tau_1, \tau_3$ . LO-criticality tasks:  $\tau_2, \tau_4$ .

## Schedulability with mode transitions

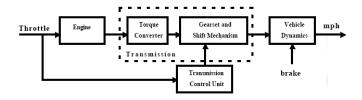

- **Example:** schedule the task set  $\{\tau_1, \ldots, \tau_4\}$ .
- ▶ HI-criticality tasks:  $\tau_1, \tau_3$ . LO-criticality tasks:  $\tau_2, \tau_4$ .

- ► Mode transitions: potential deadline misses.
- ► Time drifts when tasks are data-dependent...

## Designing safety-critical applications thanks to data-flows

- Models of Computation: data-flow & Directed Acyclic Graphs (DAGs).
  - ▶ Deterministic communication patterns.
  - ▶ Boundedness in memory, deadlock/starvation freedom...
- ▶ Industrial tools based on these model (e.g. Simulink, SCADE).
  - ► Code generation, automatic deployment into architecture.

Research Context

#### Problem Statement

Scheduling MC-DAGs on multi-cores

Case Study

Performance tests

## Problem statement: scheduling data-dependent MC tasks

- ► MC scheduling is intractable: **NP-hard** problem<sup>3</sup>.
- Multiple DAG scheduling in multi-core architectures: NP-complete problem<sup>4</sup>.

Industrial systems with **both**: MC task + DAGs

<sup>&</sup>lt;sup>3</sup>Sanjoy Baruah. "Mixed criticality schedulability analysis is highly intractable". In: 2009. URL: http://www.cs.unc.edu/~baruah/Submitted/02cxty.pdf.

<sup>&</sup>lt;sup>4</sup>Yu-Kwong Kwok and Ishfaq Ahmad. "Static scheduling algorithms for allocating directed task graphs to multiprocessors". In: ACM Computing Surveys 31.4 (1999).

## Problem statement: scheduling data-dependent MC tasks

- ► MC scheduling is intractable: **NP-hard** problem<sup>3</sup>.
- Multiple DAG scheduling in multi-core architectures: NP-complete problem<sup>4</sup>.

#### Industrial systems with **both**: MC task + DAGs

#### Existing works and current limitations

- ► For DAGs: List Scheduling efficient heuristic.
  - No variations in execution time in the literature.
  - No mode transitions for the system.
- ► For MC task sets: many different scheduling policies.
  - Rarely take into account data-dependencies (DAG).
  - ▶ When they do, **systems are overdimensioned... again!**

<sup>&</sup>lt;sup>3</sup>Baruah, "Mixed criticality schedulability analysis is highly intractable".

<sup>&</sup>lt;sup>4</sup>Kwok and Ahmad, "Static scheduling algorithms for allocating directed task graphs to multiprocessors".

Problem Statement

Scheduling MC-DAGs on multi-cores MC-correct schedules for MC-DAGs Safe mode transition property Meta-heuristic for MC-DAGs

Case Study

Performance tests

#### MC-correct schedules for MC-DAGs on multi-cores

#### Definition

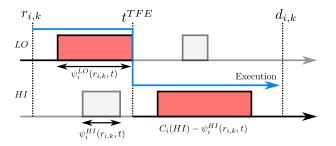

A **MC-correct**<sup>5</sup> schedule is one which guarantees:

- 1. **Condition LO-mode**: If no vertex of any MC-DAG executes beyond its  $C_i(LO)$  then all the vertices complete execution by their deadlines.
- 2. **Condition HI-mode**: If no vertex of any MC-DAG executes beyond its  $C_i(HI)$  then all the vertices designated as being of HI-criticality complete execution by their deadlines.

<sup>&</sup>lt;sup>5</sup>Sanjoy Baruah. "The federated scheduling of systems of mixed-criticality sporadic DAG tasks". In: Real-Time Systems Symposium. IEEE. 2016.

## Safe mode transitions general property

- ► Intuition: At any instant t, HI task execution time given in LO mode at least equal to the execution time given in HI mode.
- $\psi_i^{\chi}(t_1, t_2)$ : cumulative execution time given to task  $\tau_i$  in mode  $\chi$  from  $t_1$  to  $t_2$ .

# Safe Transition Property $\psi_i^{LO}(r_{i,k},t) < C_i(LO) \implies \psi_i^{LO}(r_{i,k},t) \ge \psi_i^{HI}(r_{i,k},t). \quad (1)$

## Meta-heuristic for MC-DAGs Scheduling

- Solve the complex scheduling problem off-line: computing static scheduling tables.
  - Easier to verify and have certified.
  - **Easier** to calculate  $\psi_i^{\chi}$ , enforce **Safe Transition Property**.

#### MH-McDag

- 1. Compute static scheduling in HI-criticality mode.
- Compute static scheduling in LO-criticality mode, enforcing Safe Transition Property.

Produces MC-correct schedulers for MC-DAGs.

- Existing multi-core schedulers can be adapted to produce MC-DAG schedulers.
  - ► Global-Least Laxity First and Global-Earliest Deadline First.

**Problem Statement** 

Scheduling MC-DAGs on multi-cores

Case Study

Unmanned Air Vehicle for field exploration Efficient implementations of  $\rm MH\text{-}MCDAG$ 

Performance tests

## Case Study: unmanned air vehicle (UAV)

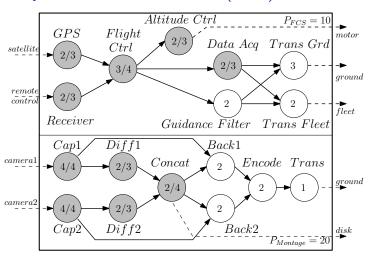

Figure 1: UAV with a Flight Control System and image processings

$$V_{max} = U_{FCS} + U_{Montage} = 1.8 + 1.05 = 2.85.$$

## Application of the federated approach

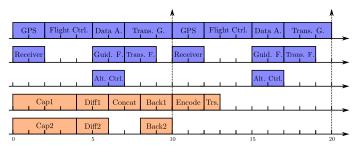

Figure 2: Five cores required for the federated scheduling approach<sup>5</sup>

#### Limitations

- 1. Single DAG has exclusive access to a cluster of cores.
- 2. HI tasks scheduled ASAP in the LO-criticality mode.
  - Respects Safe Trans. Prop. but...
  - ► LO-criticality task scheduling too constrained.
  - ▶ No longer necessary with **Safe Trans. Prop.**

## How to improve resource usage with MC-DAGs?

#### Two main strategies

- Adopt a global multi-core scheduling
  - → MC-DAGs share cores (better resource usage)
- As late as possible (ALAP) policy in the HI mode
  - ightarrow Relax HI-criticality tasks execution in the LO mode.

## **Genericity** of our implementation (G-ALAP)

- Deadlines (based on Global-Earliest Deadline First).
- Laxities (based on Global-Least Laxity First).

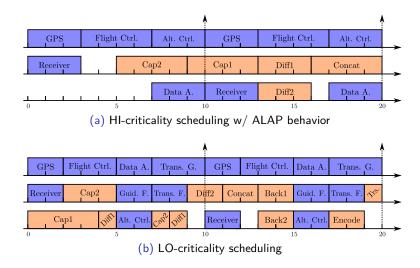

## Earliest deadline priority ordering

- Ready task jobs sorted by a "virtual deadline".
- ▶ Virtual deadline for a job k of task  $\tau_i$  in mode  $\chi$ :

$$D_{i,k}^{\chi} = d_{i,k} - CP_i^{\chi}. \tag{2}$$

- $ightharpoonup d_{i,k}$  deadline of the k-th activation of the MC-DAG.
- $ightharpoonup CP_i^{\chi}$  critical path to the vertex.

## Computed scheduling tables w/ G-ALAP-EDF

From five cores to three cores

## Laxity-based priority ordering

- Ready tasks sorted by their laxities.
- ▶ Laxity for a job k of task  $\tau_i$ :

$$L_{i,k}^{\chi}(t) = d_{i,k} - t - (CP_i^{\chi} + R_{i,k}^{\chi}).$$
 (3)

- $ightharpoonup d_{i,k}$  deadline of the k-th activation of the MC-DAG.
- t current time slot.
- $ightharpoonup CP_i^{\chi}$  critical path to the vertex.
- $ightharpoonup R_{i,k}^{\chi}$  remaining execution time.
  - ▶ Initialized with  $C_i(LO)$  or  $C_i(HI)$ .

Performance tests
MC-DAG generation
Acceptance rate results

## MC-DAG generation

- Unbiased random generation of MC-DAGs.
  - Avoid particular DAG shapes<sup>6</sup>.
  - System's utilization is uniformly distributed among vertices<sup>7</sup>.
- Configurable parameters:
  - Edge probability.
  - Number of vertices.
  - Number of MC-DAGs.
  - Utilization of the system.
  - Ratio HI/LO-criticality tasks.
- Open source framework<sup>8</sup>.

<sup>&</sup>lt;sup>6</sup>Takao Tobita and Hironori Kasahara. "A standard task graph set for fair evaluation of multiprocessor scheduling algorithms". In: *Journal of Scheduling* 5.5 (2002), pp. 379–394.

 $<sup>^{7}</sup>$ Enrico Bini and Giorgio C Buttazzo. "Measuring the performance of schedulability tests". In: Real-Time Systems Symposium 30.1 (2005).

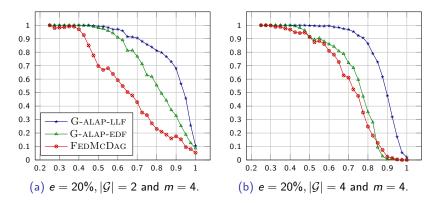

<sup>8</sup>MC-DAG framework - https://github.com/robertoxmed/MC-DAG

## Experimentation setup

- Generated large number of MC systems (1000 systems/configuration).
- Fixed the number of cores and vertices.
- Vary the utilization of the sysetem.
- Vary the number of MC-DAGs.
- Vary the density of the graph (probability to have an edge).
- Measured the acceptance rate in function of the normalized utilization.

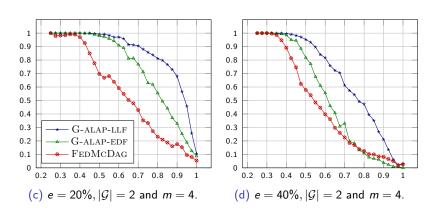

## Significant performance increase

 Comparison between our G-ALAP implementations and FEDMcDAG<sup>5</sup>.

Better schedulability when the number of MC-DAGs increases.

## Significant performance increase

When MC-DAGs are denser (parameter e):

- ▶ More difficult to schedule a MC system.
- Still better schedulability than existing approaches.

Case Study

Performance tests

## Conclusion on MC-DAG scheduling

- Designed a meta-heuristic to obtain various schedulers for DAGs on Mixed-Criticality systems.
- Meta-heuristic proven to be correct:
  - Schedulability on both modes (HI & LO).
  - ► Safe mode transitions to higher criticality mode.
- Our implementations outperform the state of the art.
  - ► More systems are schedulable considering a given architecture.
  - ► Good acceptance rate even when the utilization is high.

#### Perspectives

- Support an arbitrary number of criticality levels.
- Perform benchmarks on number of preemptions.

## Entailed number of preemptions

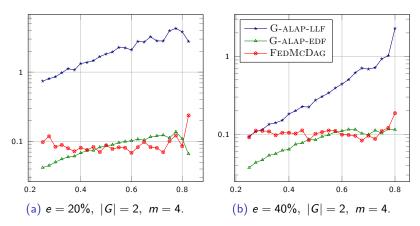

Figure 3: Average number of preemptions per job (log scale)

Number of preemptions for systems schedulable with all methods.
